Introduction: Motivation

Counterparty Credit Risk & CVA are a key focus in the derivatives market

Degree of influence 2021: XVA marks the spot

Research into valuation adjustments is back on quants' to-do list

Basel III heralds wild CVA capital swings

XVAs ate \$401m of JPMorgan's revenues in 2020

CVA desks arm themselves for the next crisis

March's volatility forces dealers to fine-tune hedging strategies

Russian invasion stirs up 'perfect storm' for XVA desks

Declining credit quality of Russian companies and spike in inflation threaten CVA and FVA double-whammy for banks

Counterparty risk capital charges up 20% at top UK banks

From Risk.net

Introduction: Definitions

What is Counterparty Credit Risk (CCR)?

...the risk that the counterparty to a transaction could default before the final settlement of the transaction's cash flows. [Basel CRE50, 50.1]

- Applies to **derivatives** transactions.
 - Primarily in the **Over-the-Counter** (OTC) market
- Why is this special?
 - **Bi-lateral** credit risk
 - **Uncertain** exposure: Market contingent credit risk
 - **Contagion**: Back-to-back transactions entail counterparty risk
- Drivers:
 - Default probability, market volatility, portfolio size, maturity

Introduction

The OTC Derivatives Market

Key Participants (Counterparty):

- Banks
- Hedge funds
- Other financial institutions
 - Pension funds
 - Broker-dealers
- Corporate Clients
- Governments and government agencies
- Regulators

Outstanding OTC derivatives

In trillions of US dollars

Introduction: Risk Management

How is Counterparty Credit Risk managed?

Risk Limits

- **Credit risk officers** monitor individual counterparties
- Metrics
 - **Potential future exposure**
 - Stress losses

Collateral

- Hold high quality assets to offset credit risk
- Collateral types
 - **Variation Margin**
 - **Initial Margin**
- Central Counterparties

Pricing

- **CVA trading team** hedges credit risk
- CVA:
 - **Credit Valuation Adjustment**
 - Cost of hedging
 - Charged to clients

Capital

- Regulators set minimum **capital requirements** to protect against credit risk
- **“Basel Rules”**
 - Default RWA
 - CVA RWA

Foundations: Outline

Exposure

- How much could we lose upon counterparty default?
 - Expected Exposure Profile, Potential Future Exposure

Examples

- What does the expected exposure profile look like?
 - Forwards, Swaps

Mitigation

- How can we reduce the exposure?
 - Netting, Collateral

Foundations: Forward MTM

MTM and Future MTM

- Initial MTM: $V(0)$
- Future MTM: $V(t)$
- $V(t)$ is the risk-free value (mark-to-market) of the trade at time t .
- For $t > 0$, $V(t)$ is not known and hence is a random variable.

Portfolio with two trades with Fixed Cash Flow:

Date of Pricing is 23rd April 2025

- Trade 1 : 1,000,000 USD; Maturity = 1Y (23rd April 2026)
- Trade 2 : 1,000,000 USD ; Maturity = 2Y (23rd April 2027)
- Portfolio Value = MTM(Trade 1) + MTM(Trade 2)
- Portfolio Initial MTM = 1,849,818 USD-? **Why not 2,000,000 ?**
- **Future MTM(24 April 2026) ~1,00000**

Marginal Deals

Trade Name	Credit End Date	▲ Recalc MTM
trade2y_Rec 0 USD / Pay -1,000,000 US...	04/23/2026	902,938.57
trade2y_Rec 1,000,000 USD / Pay 0 USD...	04/23/2025	946,880.24

$$MTM = V(0) = \mathbb{E}_0^Q[D_0(T)\Phi(T)]$$

$D_0(T)$ = Discount Factor

$\Phi(T)$ = Payoff : e.g. 1,000,00 USD

Future MTM $= V(t) = \mathbb{E}_t^Q[D_t(T)\Phi(T)]$
-> Scenario dependent. Because we don't know the value of asset at future date "t"

Foundations: Forward MTM

$Future\ MTM = V(t) = \mathbb{E}_t^Q[D_t(T)\Phi(T)]$
-> Scenario dependent. Because we don't know the value of asset at future date "t"

V(Portfolio, t=20th April 2026)

V(Portfolio, t=21st May 2027)

Foundations: Forward MTM

Expected Future MTM vs Expected Discounted Future MTM
Notice Martingale Behaviour

$$\begin{aligned}
 \mathbb{E}_0^Q [D_0(\tau)V_{RF}(\tau)] &= \mathbb{E}_0^Q [D_0(\tau)\mathbb{E}_\tau^Q [D_\tau(T)\Phi(T)]] \\
 &= \mathbb{E}_0^Q [\mathbb{E}_\tau^Q [D_0(\tau)D_\tau(T)\Phi(T)]] \\
 &= \mathbb{E}_0^Q [D_0(T)\Phi(T)] \\
 &= V_{RF}(0) \\
 &= \text{Initial MTM}
 \end{aligned}$$

Foundations: Forward MTM

Expected Exposure Profile

- Curve of expected exposure for all future t as of today t_0 :
 - $EE(t) = \mathbb{E}_0^*[E(t)|t = \tau] = \mathbb{E}_0^*[V(t)^+|t = \tau]$
- **Conditional on counterparty defaulting at time $t = \tau$**
- If exposure is independent of default:
 - $EE(t) = \mathbb{E}_0^*[V(t)^+]$

Peak (97.5%) : Exposure at default Metrics used for Risk Management

Foundations: Peak 97.5%

Peak (97.5%) : Metrics used for Risk Management.

Peak is very sensitive to volatility of underlying asset.

And can be much higher than Average.

97.5% = Average + 2 x Standard Deviation

• **Typical “square-root” profile:**

$$\text{Peak}(t, 97.5\%) \sim \sigma \sqrt{t}$$

Marginal Deals				
Trade Name	Maturity Date	Product Type	Pay CCY	Receive CCY
fxfwdUSDINR_Rec 1,000,000 USD / Pay 84,000,000 INR (M...	04/22/2025	FX FWD	INR	USD

Foundations: Exposure

Exposure

- Loss on default assuming zero recovery
- $E(t) = \max(V(t), 0) = V(t)^+$
- Single trade with no collateral
- $V(t)$ is the risk-free value (mark-to-market) of the trade at time t

Why the max?

Current Exposure: $E(t_0) = V_0^+$

- Amount we would lose if default happened today

Expected Exposure Profile

- Curve of expected exposure for all future t as of today t_0 :
 - $EE(t) = \mathbb{E}_0^*[E(t)|t = \tau] = \mathbb{E}_0^*[V(t)^+|t = \tau]$
- **Conditional on counterparty defaulting at time $t = \tau$**
- If exposure is independent of default:
 - $EE(t) = \mathbb{E}_0^*[V(t)^+]$

What is the correct measure for the expectation?

Foundations: Exposure

$$E(t) = \max(V(t), 0) = V(t)^+$$

Foundations: Exposure: Forward

Exposure profile of a forward contract

- Expected Exposure: $EE(t) = \mathbb{E}_0[V(t)^+]$
- Forward on stock S_t with maturity T :
 - $V(t) = \mathbb{E}_t[S_T - k] = S_t - k$
 - Assume zero interest rates and: $dS_t = \sigma S_t dW_t$
- $EE(t) = \mathbb{E}_0[V(t)^+] = \mathbb{E}_0[(S_t - k)^+] = BS_{S_0, k}(\sigma, t)$
- **Expected exposure of forward is value of option!**
 - Exposure increases up to maturity of the trade
 - Uncertainty in value greater in future
 - $BS_{S_0, k}(\sigma, t) \approx \frac{1}{2\sqrt{2\pi}} S_0 \sigma \sqrt{t}$
 - (for small σ and t and $S_0 = k$)
 - **Typical “square-root” profile: $EE(t) \sim \sqrt{t}$**

Exercise: Derive the expected exposure for an option

$\sigma = 30\%$

Foundations: Exposure: Cashflow Stream

Exposure profile of a stream of cashflows (swap)

- Typical for a large portfolio
- Value of continuous stream of cashflows x_u with maturity T:
 - $V(t) = \mathbb{E}_t \left[\int_t^T x_u du \right] = x_t(T - t)$ and $V_0 = x_0 T$
 - Assume: $r = 0$ and $dx_u = \sigma^x dW_u$ (x_t is a martingale)
- $EE(t) = \mathbb{E}_0 [(T - t)x_t^+] = (T - t)\mathbb{E}_0 [(x_0 + \sigma W_t)^+]$
 - $EE(t) = (T - t)\sigma^x \sqrt{t} (\tilde{x}_0 \Phi(\tilde{x}_0) + \phi(\tilde{x}_0))$ with $\tilde{x}_0 = \frac{x_0}{\sigma^x \sqrt{t}}$

At the Money:

- Exposure profile has typical hump shape

In the Money:

- Linearly decreasing profile starting at today's value

Out of the Money:

- No exposure

Expected Exposure for Cashflow Stream

$\sigma^x = 1\%$

Foundation: Other Exposure Metrics

Expected Exposure

- Fundamental input to XVA calculations
- Also used in Basel Default RWA definition
 - Exposure at Default (EAD) is function of EE in first year

Potential Future Exposure (PFE)

- “Worst case loss” defined as quantile in exposure distribution
- Used to set credit risk limits
- PFE at quantile q and time t defined by:
 - $\text{Prob}[E(t) < \text{PFE}_q(t)] = q$
 - Typically, $q = 99\%$
- If $V(t)$ is Gaussian with zero mean, then
 - $\text{PFE}_{99\%}(t) \approx 5.8 \cdot \text{EE}(t)$

Foundations: Risk Mitigation: Netting

What is the exposure of portfolio with multiple trades?

- Depends on “**netting agreement**” (ISDA agreement)

Netting is contractual agreement allowing the value of multiple trades with one counterparty to be added prior to making a default claim

- Exposure without netting: $EE(t) = \sum_i \mathbb{E}_0^*[V_i(t)^+]$
- Exposure with netting: $EE(t) = \mathbb{E}_0^*[(\sum_i V_i(t))^+]$
- Netting is always risk reducing
 - Can net across all product types with single counterparty (bi-lateral netting)
- Benefit scales with portfolio size
 - Assume N trades with independent, Gaussian distributions for the values V_i
 - Expected exposure without netting scales like N ; with netting scales like $\sqrt{N}$
- **To benefit, we need to manage Counterparty Risk centrally**
 - Exposure needs to be calculated at the counterparty portfolio level (netting set)

$$\underbrace{(V_1(t) + V_2(t))^+}_{\text{Exposure with netting}} < \underbrace{V_1(t)^+ + V_2(t)^+}_{\text{Exposure without netting}}$$

	Trade Values				Exposure			
	Trade Values		Exposure		Trade Values		Exposure

P1	20		5		25		25	
P2	20		-5		20		15	
P3	-20		5		5		0	

Foundations: Risk Mitigation: Collateral

Collateral is cash or assets posted to offset default risk

- The **Credit Support Annex (CSA)** defines the collateral terms
 - Can be cash or high quality assets (e.g. government securities)
 - Collateral amounts are updated on a regular basis
 - Typically have a daily collateral frequency
 - Posting amount depends on the amount and direction of the risk
 - Collateral can be bi-lateral or uni-lateral
 - Collateral can be re-used: It can be “re-hypothecated”
- Collateral directly reduces the exposure:
 - $E(t) = (V(t) - C(t))^+$
 - where $C(t)$ is the collateral held at time t
- Two main types of collateral:
 - Variation Margin (VM)
 - Initial Margin (IM)
- **However**, large collateral calls can cause distress
 - Can transmit default risk

Total VM received by Phase-one Firms (US\$ billions), ISDA Margin Survey 2022

Regulatory IM and IA received by Phase-one Firms (US\$ billions)

Foundations: Risk Mitigation: Variation Margin

Variation Margin (VM)

- Collateral to cover mark-to-market (MtM) moves.
- Typically posted daily and equal to the MtM on that day
- If a counterparty defaults, there will be a delay between the last collateral payment and the default settlement
 - This is the “margin period of risk (MPoR)” Δ
 - Also referred to as the “cure period”
- Exposure given by:
 - $E(t) = (V(t) - C(t))^+ = (V(t) - V(t - \Delta))^+$
- Retain “cure period risk”
 - Sensitive to MtM forward volatility over cure period Δ
- Can become important in stress scenarios
- Variation margin is standard between financial counterparties

Foundations: Variation Margin Exposure

$$E(t) = \max(V(t), 0) = V(t)^+$$

$$E(t) = (V(t) - C(t))^+ = (V(t) - V(t - \Delta))^+$$

09/11/2024	15,139.23	3,129.10

Foundations: Risk Mitigation: Initial Margin

Initial Margin (IM)

- Additional collateral to cover cure period risk
- Can be static or dynamic
- $E(t) = (V(t) - C(t))^+ = (V(t) - V(t - \Delta) - IM(t))^+$
- IM is usually calculated using risk sensitive models
 - E.g. quantile in distribution of $\Delta V(t)$
- IM is mandated by regulators for large financial firms
 - Standard Industry Margin Model (SIMM)
- IM is charged by CCPs
- Residual exposure with IM is difficult to model
 - Required to achieve regulatory capital benefit

Foundations: Recovery and Loss

Exposure is the amount that is owed upon counterparty default

- This is the basis of **default claim** made to the counterparty
 - Also referred to as “**close-out amount**”
- Remaining assets of counterparty will be distributed to creditors
- Derivatives claims are treated like loans (not bonds)
 - They are “**pari passu**” with loans
- Actual loss on default is a fraction of the claim
- The amount recovered is given by the **recovery rate** R^C
 - **Loss given default:** $\text{LGD} = (1 - R^C)$
 - Typically: $R^C \approx 40\%$
- Loss is given by: $L(t) = (1 - R^C)E(t)$
- *What is the value or cost of the expected loss?*

Valuation: Overview

CVA

- What is the value of the expected loss?
- How do we adjust derivative valuation?

Exa
mpl
es

- How do we calculate CVA?
- Approximations and intuition

W
WR

- What is Wrong-Way-Risk?
- How does it impact exposure?

Valuation: CVA Definition

CVA: **Credit Valuation Adjustment** = Expected loss due to counterparty default

- CVA captures the cost or value associated with a potential default loss
 - Cost of hedging the risk
- CVA is an add-on to the risk-free value
- Define CVA as the value of a derivative with payoff equal to loss on default

$$\text{CVA} = \mathbb{E}^Q [D_0(\tau)(1 - R^C)E(\tau)\mathbb{I}_{\tau < T}]$$

- $D_t(T) = e^{-\int_t^T r_s ds}$ is the stochastic discount factor with riskless rate r_t
 - τ is the default time of the counterparty and T is the maturity of the derivative
 - $\mathbb{I}$ is the indicator function
 - $\mathbb{E}^Q$ is the expectation in the risk neutral measure
- This is “unilateral” CVA as our own default is not considered

Valuation: CVA as Valuation Adjustment

CVA is an adjustment to the risk-free trade value V_{RF}

- $V_{tot} = V_{RF} - CVA$
- Allows separation of trading desk and CVA desk

Derivation for derivative with payoff $\Phi(T)$ at maturity T :

$$V_{tot} = \underbrace{\mathbb{E}_0^Q [D_0(T)\Phi(T)\mathbb{I}_{\tau > T}]}_{\text{no default}} + \underbrace{\mathbb{E}_0^Q [D_0(\tau)(R^C V_{RF}(\tau)^+ - V_{RF}(\tau)^-)\mathbb{I}_{\tau < T}]}_{\text{default}}$$

$$\begin{aligned} V_{tot} &= \mathbb{E}_0^Q [D_0(T)\Phi(T)\mathbb{I}_{\tau > T}] + \mathbb{E}_0^Q [D_0(\tau)V_{RF}(\tau)\mathbb{I}_{\tau < T}] - \mathbb{E}_0^Q [D_0(\tau)(1 - R^C)V_{RF}(\tau)^+\mathbb{I}_{\tau < T}] \\ &= \mathbb{E}_0^Q [D_0(T)\Phi(T)] - \mathbb{E}_0^Q [D_0(\tau)(1 - R^C)V_{RF}(\tau)^+\mathbb{I}_{\tau < T}] \\ &= V_{RF} - CVA \end{aligned}$$

$$\begin{aligned} \mathbb{E}_0^Q [D_0(\tau)V_{RF}(\tau)\mathbb{I}_{\tau < T}] &= \mathbb{E}_0^Q [D_0(\tau)\mathbb{E}_\tau^Q [D_\tau(T)\Phi(T)]\mathbb{I}_{\tau < T}] \\ &= \mathbb{E}_0^Q [\mathbb{E}_\tau^Q [D_0(\tau)D_\tau(T)\Phi(T)\mathbb{I}_{\tau < T}]] \\ &= \mathbb{E}_0^Q [D_0(T)\Phi(T)\mathbb{I}_{\tau < T}] \end{aligned}$$

$$V_{RF}(t) \equiv \mathbb{E}_t^Q [D_t(T)\Phi(T)]$$

$$\begin{aligned} V_{RF}(\tau)^- &\equiv -\min(V_{RF}(\tau), 0) \\ &= -(V_{RF}(\tau) - V_{RF}(\tau)^+) \end{aligned}$$

CCR Basics

From CCR to CVA

CVA stands for **Credit Valuation Adjustment**

- Defined as the value of the expected loss
- Loss on default of counterparty C:
 - $L(t) = (1 - R^C)E(t)$
 - Where R^C is the **recovery rate**

Uni-lateral CVA

- Assume we are riskless:

$$UCVA = \mathbb{E}_0^Q [D_0(\tau)(1 - R^C)E(\tau)\mathbb{I}_{\tau < T}]$$

Default time: τ

Discount factor: $D_t(T) = e^{-\int_t^T r_s^* ds}$

- Can be written as time integral:

$$UCVA = (1 - R^C) \int_0^T \lambda^C(t) Q^C(t) Z(t) EE^+(t) dt$$

Default intensity: λ^C

Survival probability: $Q^C(t) = e^{-\int_0^t \lambda^C(s) ds}$

Zero coupon bond price: $Z(t) = \mathbb{E}^Q[D_0(t)]$

EE & Default Prob

$\text{Prob}[t < \tau^C < t + dt] = \lambda^C(t)Q^C(t)$

Valuation: CVA as a stream of CDS

CVA is a time integral of the expected exposure

- $CVA = \mathbb{E}_0^Q [D_0(\tau)(1 - R^C)E(\tau)\mathbb{I}_{\tau < T}]$
- $CVA = (1 - R^C) \int_0^T \mathbb{E}_0^Q [D_0(t)E(t)|\tau = t]P(\tau = t)dt$
- $CVA = (1 - R^C) \int_0^T Z(t)EE(t)P^C(\tau = t)dt$

$$CVA = (1 - R^C) \int_0^T \lambda^C(t)Q^C(t)Z(t)EE(t)dt$$

$$CVA = (1 - R^C) \int_0^T \lambda^C(t)e^{-\int_0^t (r(s) + \lambda^C(s))ds} EE(t)dt$$

- CVA can be valued as the contingent leg of a CDS with time varying notional
- CVA can be replicated with a term structure of CDS

Where:

- $Z(t)$ is the zero-coupon bond price
- $Z(t) = \mathbb{E}^Q [D_0(t)] = e^{-\int_0^t r(s)ds}$
- Here $r(s)$ is the forward rate
- $EE(t)$ is the calculated in the “t-forward” measure
- $EE(t) = \mathbb{E}^Q \left[\frac{D_0(t)}{Z(t)} E(t) | \tau = t \right] = \mathbb{E}^F [E(t) | \tau = t]$
- $P(\tau = t)dt$ is the default prob in interval $(t, t+dt)$
- $P^C(\tau = t)dt = \lambda^C(t)Q^C(t)dt = \lambda^C(t)e^{-\int_0^t \lambda^C(s)ds}dt$
- $Q^C(t) = e^{-\int_0^t \lambda^C(s)ds}$ is the counterparty survival probability
- $\lambda^C(t) = -\frac{d}{dt} \ln Q(t)$ is the forward default rate of the counterparty

Valuation CVA Hacks

To gain intuition it is useful to simplify CVA formula

- $CVA = (1 - R^C) \int_0^T \lambda^C(t) e^{-\int_0^t (r(s) + \lambda^C(s)) ds} EE(t) dt$
 - Assume λ and r are small, i.e. discount and survival factors are close to 1
 - Assume $\lambda^C(t) = \lambda_0^C$ is constant
 - Counterparty credit spread $s^C \approx (1 - R^C) \lambda^C$
- $CVA = s^C \cdot \overline{EE} \cdot T$ where
- $\overline{EE} \equiv \frac{1}{T} \int_0^T EE(t) dt$ is the average expected exposure

Valuation: CVA Examples: ATM Forward

$$CVA = s^c \cdot \overline{EE} \cdot T$$

- Expected Exposure:

- $EE(t) = BS_{S_0, k}(\sigma, t) \approx \frac{1}{2\sqrt{2\pi}} \sigma \sqrt{t}$
- Assume $S_0 = k = 1$

- $\overline{EE} = \frac{1}{T} \int_0^T \frac{1}{2\sqrt{2\pi}} \sigma \sqrt{t} dt = \frac{1}{3\sqrt{2\pi}} \sigma \sqrt{T} = \frac{2}{3} EE_{\max}$

- $CVA = \frac{1}{3\sqrt{2\pi}} s^c \cdot \sigma \cdot T^{\frac{3}{2}}$

- For typical values: $s^c = 100\text{bps}$, $\sigma = 30\%$, $T=5\text{y}$
 - $CVA \approx 45\text{bps}$

Expected Exposure for ATM Forward

CVA for ATM Forward

Valuation: CVA Examples: Cashflow Stream

At the Money (ATM)

- $EE(t) = \frac{1}{\sqrt{2\pi}} \sigma \sqrt{t}(T-t)$
- $\overline{EE} = \frac{1}{T} \int_0^T EE(t) dt = \frac{4}{15\sqrt{2\pi}} \sigma^x T^{\frac{3}{2}} = \frac{2\sqrt{3}}{5} EE_{\max}$
- $CVA = s^c \cdot \overline{EE} \cdot T = \frac{4}{15\sqrt{2\pi}} s^c \cdot \sigma^x \sqrt{T} \cdot T^2$
- $CVA \approx 5.2\%$ or 17bps running

In the Money (ITM)

- $EE(t) = V_0 \left(1 - \frac{t}{T}\right)$
- $\overline{EE} = \frac{1}{2} V_0$
- $CVA = \frac{1}{2} s^c \cdot V_0 \cdot T$
- $CVA/V_0 \approx 15\%$

Typical values:
 $s^c = 100\text{bps}$,
 $\sigma^x = 1\%$,
 $T=30\text{y}$

Expected Exposure for Cashflow Stream

CVA for Cashflow Stream

Modelling: Overview

CVA is typically calculated centrally and at a counterparty portfolio level

Modelling: Spreads and Recoveries

Default Probabilities

- Use market implied counterparty default probabilities for valuation
- Bootstrap probabilities from CDS spreads if available
 - $\text{Spread} = (1 - R)\lambda$
- Few counterparties will have liquid CDS
- Use “proxy” spreads
 - Related counterparties
 - Indices
- Or interpolate spreads using:
 - Rating, industry & sectorial classifications
 - Bond data. Equity?
 - Use regression or ML techniques
- Risk management will rely on indices or proxy CDS (macro hedging)

Recovery rates

- Market credit spreads typically imply a fixed recovery of around 40%.
- Market recovery rate should be used for bootstrapping default probabilities
- Market recovery rates refer to bond recoveries
- $$\text{CVA} = (1 - R^C) \int_0^T Z(t) EE(t) \lambda^C(t) e^{-\int_0^t \lambda^C(s) ds} dt$$
- Recovery rate for derivative may be different
 - Derivatives are bi-lateral instruments and typically *pari passu* with loans

CVA Practice: Charging and Allocation

To capture portfolio level collateral terms and benefit from netting:

- Calculate CVA at counterparty level
- Calculate and risk manage CVA centrally
- CVA desk insures defaults in return for the CVA charge

However, client charges are at trade level and managed by business units

- Require trade allocation for CVA
- Incremental (marginal) exposure for trade A:
 - $EE_A(t) = \mathbb{E}[(V_A(t) + V_{tot})^+] - \mathbb{E}[V_{tot}^+]$
 - Portfolio value $V_{tot} = \sum_i V(t)$
- Depends on order of trades
- Requires optimization of compute & memory overhead
 - Precompute V_{tot} for each counterparty

CVA Practice: Risk Management

A CVA trading desk will calculate numerous metrics for risk management

- CVA Greeks/Sensitivities: $\frac{\partial CVA}{\partial X_i}$
- P&L Explain and Predict: $CVA(t) \approx CVA(t - \Delta t) + \sum_i \frac{\partial CVA}{\partial X_i} \Delta X_i$
- CVA VaR and Stress: quantile in CVA distribution or CVA in specific stress scenario

Spread Risk

- CVA is linear in spreads. Risk is efficient to compute
- Hedge with CDS either single name or index (macro hedging)
- Can only hedge idiosyncratic default risk when counterparty has liquid CDS instruments
- Otherwise, can only hedge spread MtM risk

Market Risk

- Large number of risk factors. Each risk factor sensitivity requires full re-valuation
- Equivalent to exotic derivative hedging
- Very expensive if not optimized e.g. using analytic sensitivities (AAD)
- Focus on key risk drivers, e.g. IR, FX. Hedge using swaps and options

CVA Practice: Performance

- Credit Exposure calculations are highly compute intensive.
- E.g. 1M trades, 10k paths, 100 time points -> 1Trillion evaluations
 - Assume 1ms per trade -> require 275k CPU hours
 - Require cutting edge compute architecture:

Code Optimization

- Fast pricers
- Monte Carlo variance reduction
- Analytical Adjoint Differentiation (AAD)
- Trade compression

Hardware

- Parallelization
- GPUs
- Cloud Computing
- Large memory machines
- Quantum computing...

Conclusion (CVA)

- Counterparty risk is the default risk for derivatives portfolios
- CVA is an adjustment to the risk-free trade value to account for counterparty risk
- CVA calculation is similar to pricing an exotic derivative
- Presence of netting and collateral requires portfolio level risk management
- Exposure calculations are highly compute intensive and require advanced software and hardware
- CVA risk management in particular focus in times of crisis

FVA

Funding

What is Funding?

Funding is the act of providing resources (money) to finance a business

- Two types of funding: Equity and Debt
 - A company can issue shares or sell bonds to raise money
- Typical example
 - A bank makes a \$100 loan to a corporate client.
 - To make the loans the bank will need to raise funds (typically via deposits – a form of debt)
- Derivatives business
 - Holding and risk managing a derivative to maturity requires ongoing and dynamic funding
 - This is represented by the “bank account” in the replicating portfolio
 - Funding for the derivatives business is provided by the **Treasury** function.
 - The Treasury charges the business a “**funding rate**” for the financing
- The funding rate is based on the rate that the firm can borrow money in the inter-bank market
- All derivatives funding is assumed to be via debt

Funding The Funding Rate

The funding rate is linked to the default probability of the firm

- $r^F = r^* + s^F$, where $s^F = (1 - R)\lambda$ is the funding spread
- The spread is compensation for the expected loss due to default

BCVA & DVA

From Uni-lateral to Bi-lateral CVA

Uni-lateral CVA: UCVA

- So far we have assumed that we are “risk free”
- But we are also a counterparty!
- Uni-lateral CVA breaks valuation symmetry

What happens if we default?

- Only have counterparty risk conditional on our survival
 - Adjust UCVA by our survival probability to get bi-lateral CVA: BCVA
- In default we no longer need to pay counterparty
 - This is a benefit -> Debt Valuation Adjustment (DVA)
 - Benefit is the CVA from the counterparty perspective

What is the total value?

- Expect: $V_{tot} = V^* - BCVA + DVA$
- This is symmetric between counterparties

BCVA & DVA

Bi-lateral CVA derivation 1

Consider single derivative trade with payoff $\Phi(T)$ at maturity T

- Assume both we (Bank B) and Counterparty C are risky

$$V_{tot} = \underbrace{\mathbb{E}^Q[D_0(T)\Phi(T)\mathbb{I}_{\tau_B, \tau_C > T}]}_{\text{I: no default}} + \underbrace{\mathbb{E}^Q[D_0(\tau^C)(R^C V^*(\tau^C)^+ - V^*(\tau^C)^-)\mathbb{I}_{\tau^C < T}\mathbb{I}_{\tau^C < \tau^B}]}_{\text{II: C defaults first}} \\ + \underbrace{\mathbb{E}^Q[D_0(\tau^B)(V^*(\tau^B)^+ - R^B V^*(\tau^B)^-)\mathbb{I}_{\tau^B < T}\mathbb{I}_{\tau^B < \tau^C}]}_{\text{III: B defaults first}}$$

$$\text{II} = \mathbb{E}^Q[D_0(\tau^C)V^*(\tau^C)\mathbb{I}_{\tau^C < T}\mathbb{I}_{\tau^C < \tau^B}] - \underbrace{\mathbb{E}^Q[D_0(\tau^C)(1 - R^C)V^*(\tau^C)^+\mathbb{I}_{\tau^C < T}\mathbb{I}_{\tau^C < \tau^B}]}_{\text{BCVA}}$$

$$\text{III} = \mathbb{E}^Q[D_0(\tau^B)V^*(\tau^B)\mathbb{I}_{\tau^B < T}\mathbb{I}_{\tau^B < \tau^C}] + \underbrace{\mathbb{E}^Q[D_0(\tau^B)(1 - R^B)V^*(\tau^B)^-\mathbb{I}_{\tau^B < T}\mathbb{I}_{\tau^B < \tau^C}]}_{\text{DVA}}$$

$$V^*(t)^+ \equiv \max(V^*(t), 0) \\ V^*(t)^- \equiv -\min(V^*(t), 0) \\ V^*(t) = V^*(t)^+ - V^*(t)^-$$

	τ^B	$R^B \cdot V^*(\tau^B)^+$	$-R^B \cdot V^*(\tau^B)^-$		τ^B	$R^B \cdot V^*(\tau^B)^+$	$-R^B \cdot V^*(\tau^B)^-$

FVA

FVA Decomposition

$$\begin{aligned}V^*(t)^+ &\equiv \max(V^*(t), 0) \\V^*(t)^- &\equiv -\min(V^*(t), 0) \\V^*(t) &= V^*(t)^+ - V^*(t)^-\end{aligned}$$

FVA can be positive or negative

- FVA can be split into a cost and a benefit

$$\begin{aligned}\text{FVA} &= \mathbb{E}^Q \left[D_0(\tau^B)(1 - R^B) V^*(\tau^B) \mathbb{I}_{\tau^B < T} \mathbb{I}_{\tau^B < \tau^C} \right] \\&= \underbrace{\mathbb{E}^Q \left[D_0(\tau^B)(1 - R^B) V^*(\tau^B)^+ \mathbb{I}_{\tau^B < T} \mathbb{I}_{\tau^B < \tau^C} \right]}_{\text{FCA (funding cost adjustment)}} \\&\quad - \underbrace{\mathbb{E}^Q \left[D_0(\tau^B)(1 - R^B) V^*(\tau^B)^- \mathbb{I}_{\tau^B < T} \mathbb{I}_{\tau^B < \tau^C} \right]}_{\text{FBA (funding benefit adjustment)}}\end{aligned}$$

- $\text{FVA} = \text{FCA} - \text{FBA}$
- The funding benefit has same form as DVA: $\text{FBA} = \text{DVA}$

FVA Hack for Intuition

What is the cost of funding a derivatives trade

- Floating rate note with riskless counterparty:
- Bank B will make running loss of $(r^B - r^*) = s^B$
- Where s^B is the funding spread of B and N is notional
- Cost is incurred while B is alive
- Total cost is:

Cost incurred to maturity

$$\int_0^T e^{-r^*t} Q^B(t) s^B(t) dt$$

Discount factor

B Survival Prob

Funding spread

$$s^B = \lambda^B(1 - R^B)$$

Floating rate note:

- Buy 1y floating rate note for \$1 from risk free counterparty
- Get paid quarterly coupons of risk-free rate r^*
- Get paid notional of \$1 at maturity
- To buy the note need to borrow \$1 from treasury
- Treasury will charge funding rate r^B until I pay back at maturity

$$FVA \sim \int_0^T s^B(t) Z(t) V(t) dt$$

- EP FWD MTM Profile.

$$E \left[\int_0^{\infty} e^{\int_0^u r_3(s) ds} (r_1(u) - r_2(u)) Z_u du \right]$$

- Libor (Sofr), Valuation/Collateral rate, Funding rate.

- Estimate using Numerical approximation.

$$0 = t_0 < t_1 < t_2 \cdots < t_n$$

$$\sum_{i \geq 1} E \left[-Z_{t_{i-1}} M_3(t_{i-1})^{-1} \left(\frac{M_1(t_{i-1})}{M_2(t_{i-1})} \right) \left(\frac{M_2(t_i)}{M_1(t_i)} - \frac{M_2(t_{i-1})}{M_1(t_{i-1})} \right) \right]$$
